Abstract

In this paper we address extracting slot values from internet pertinent to entities in wikipedia, which is the most popular web-based, collaborative multilingual encyclopedia on the internet. This is comparable to Freebase in a query-driven manner. Our contributions are two fold, first we design a system to efficiently find central documents on the internet that contain directly citable content regarding a given wikipedia entity; second, we design a system to extract certain slot-values of the entity from those documents. Our results demonstrate that the system is very efficient in the web scale nature of the problem: being highly memory and I/O efficient and that we can achieve high accuracy and recall for given slot values.

Introduction

Wikipedia.org (WP) is the largest and most popular general reference work on the Internet. The website is estimated to have nearly 365 million readers worldwide. An important part of keeping WP usable is to include new and current content. Presently, there is considerable time lag between the publication of an event and its citation in WP. The median time lag for a sample of about 60K web pages cited by WP articles in the *living-people* category is over a year and the distribution has a long and heavy tail Frank et al. (2013). Such stale entries are the norm in any large reference work because the number of humans maintaining the reference is far fewer than the number of entities.

Reducing latency keeps WP relevant and helpful to its users. Given an entity page, such as *wiki/Boris_Berezovsky_(businessman)*¹, possible citations may come from a variety of sources. Notable news may be derived from newspapers, tweets, blogs and a variety of different sources include Twitter, Facebook, iBlogs, arxiv, etc. The actual citable information is a small percentage of the total documents that appear on the web. The goal of this system is to read web documents and recommend citable facts for WP pages.

Previous approaches are able to find relevant documents given a list of WP entities as query nodes Balog and Ramampiaro (2013); Bonnefoy, Bouvier, and Belot (2013); Dalton and Dietz (2013); Ji and Grishman (2011); McNamee et al. (2012). Entities of three categories *person*, *organization* and *facility* are considered. This task involves processing large sets of information to determine which facts may contain references to a WP entity. This problem becomes increasingly more difficult when we look to extract relevant facts from each document. Each relevant document must now be parsed and processed to determine if a sentence or paragraph is worth being cited.

Discovering facts across the Internet that are relevant and citable to the WP entities is a non-trivial task. Here we produce an example sentence from a new website:

“Boris Berezovsky, who made his fortune in Russia in the 1990s, passed away March 2013.”

First, we must realize that there are two *Boris Berezovsky* entities in WP, one a businessman and the other a pianist. Any extraction needs to take this into account and employ a viable distinguishing policy (entity resolution). Then, we match the sentence to find a topic such as *DateOfDeath* valued at *March 2013*. Each of these operations is expensive so an intelligent efficient framework is necessary to execute these operations at web scale.

In this paper we develop an efficient query-driven slot extraction for given WP entities from a time oriented document stream. Fact or slot extraction is defined as follows: match each sentence to the generic sentence structure of [*subject* - *verb* - *adverbial/complement*] Stevens (2008), where *subject* represents the entity and *verb* is the relation type (slot) we are interested in (e.g. Table 1). The third component, *adverbial/complement*, represents the value of the entity slot. In our example sentence, the entity of the sentence is *Boris Berezovsky* and the slot we extract is *DateOfDeath* with a slot value of March 2013.

Our system contains three main components. First, we pre-process the data and build models representing the WP query entities. Next, we use the models to filter a large stream of documents so they only contain can-

Table 1: Ontology of Slots

Person	Facility	Organization
Affiliate		
AssociateOf		
Contact_Meet_PlaceTime		
AwardsWon	Affiliate	Affiliate
DateOfDeath	Contact_Meet_Entity	TopMembers
CauseOfDeath		FoundedBy
Titles		
FounderOf		
EmployeeOf		

didate citations. Lastly, we processes sentences from candidate extractions and return slot values. Overall, we contribute the following:

- Introduce a method to build models of WP name variations (Section ??);
- Built a system to filter a large amount of diverse documents using a natural language processing rule-based extraction system (Section ??);
- Extract, infer and filter entity-slot-value triples of information to be added to KB (Section ??).

System

In this section, we introduce the main components of the system. Our system is built with a pipeline architecture in mind giving it the advantage to run each section separately to allow stream processing without blocking the data flow of components (Figure 1). The three logical components include sections on *Model* for entity resolution purposes, *Wiki Citation* to annotate cite-worthy documents, *Slot Filling* to generate the actual slot values.

If we are looking to discover facts for a single WP entity, the first step is to extract aliases of the entity. We extract several name variations from the Wikipedia api and from the WP entity page. Also, if the entity type is *person* we can change the order of user names to increase coverage (e.g. ‘Boris Berezovsky’ → ‘Berezovsky, Boris’). Next, we iterator over documents in the stream and filter out all document that are not central to the entity. To extract relevant facts we perform pattern matching in each sentence that matches the entity based on a dictionary of patterns. If the sentence can activate on of the patterns in the dictionary we emit this sentence as a candidate contribution to the WP entity. With the candidate set, we infer new facts from the set and clean up the set by removing the set that violate a list of constraints such as duplicates. Lastly, we try to infer a new set of facts based on a list of rules.

Entity Model

We use Wikipedia API to automatically retrieve aliases. The API allows us to requests pages that redirect users to an entity page. For example, if a WP user tries to access the *William Henry Gates* they are sent to the page for *Bill Gates* therefore we treat these two names as

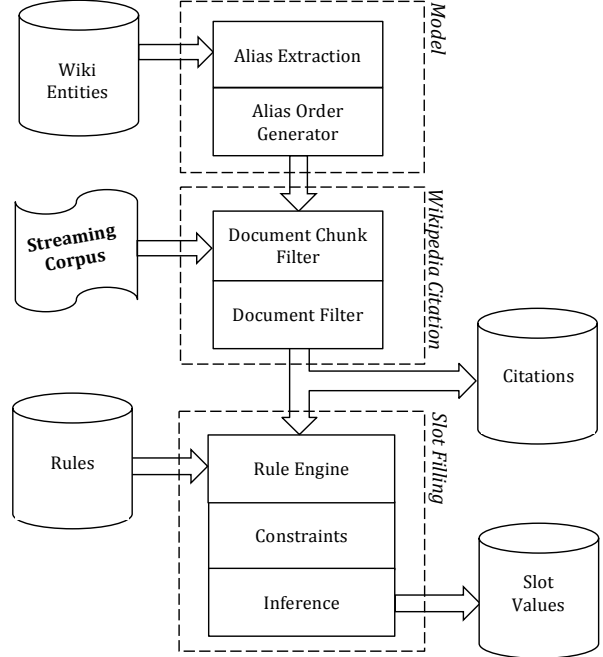

Figure 1: System Architecture. Components are logical groups noted with dotted boxes.

aliases. To extract more aliases is we parse the HTML source of a WP entity page. Then using regular expressions we extract the bold phrases of the initial paragraph as aliases. Based on our observation this is a very accurate method and it provides several entities of WP with more inline aliases from the wiki page itself. As an example, for ‘Boris Berezovski’ which was mentioned early-on, there is an alias of ‘Boris Abramovich Berezovsky’ given in bold in the wiki page which will be obtained via thi method.

We pass the full set of *person* entities through rules for generating proper name orders. This module produces various forms of writing entity names and titles. For example, *Bill Gates* can be written as *Gates*, *Bill*. This allows the system to capture various notation forms of aliases that appear in text documents.

Wikipedia Citation

The goal of this section is to use the models created to discover a set of documents that are relevant to the WP entity. As a stream of documents come in we first perform a string match between the model aliases and document text. We use this technique as a first filter with confidence because previous work has stated non-mentioning documents have a low chance of being citable in Wikipedia Frank et al. (2013). Given our large number of aliases we can be confident if an alias does not appear in a document it does not need to be cited.

Our stream system receives documents in the from of chunk files. Each chunk file contains thousands of documents. This corpus of documents is processed by a two-layer filter system referred to as *Document Chunk Filter* and *Document Filter*. The purpose of these fil-

ters is to reduce I/O cost while generating slot values for various entities. Document Chunk Filter removes the chunk files that do not contain a mention of any of the desired entities. Each chunk file may contain thousands of documents — each document is expensive to process. The Document Filter removes documents that do not contain a mention of an entity. This two-level filter allows us to perform detailed slower processing over a smaller set of documents. Not all chunk files contain mention of the entities so filtering out large chunk files early saves no I/O and processing. Document Chunk Filter discards non-mentioning chunk files and promotes chunk files as soon as an entity mention is found. The document filter additionally notes the sentences that contain entity mentions. This data is passed to the Slot Filling system.

Slot Filling

Streaming Slot Filling (SSF) extracts fact values from sentences according to a list of pattern. Table 1 list the slot relationships that we looks to extract. In Figure 1 we refer to this task as *Slot Filling*.

SSF reads documents filtered by the Wikipedia Citation step and fetches and tags sentences containing WP entities. All entities are extracted from the document using a natural language processing tool². In the next section, we describe how WP entities are matched against the set of patterns. Following, we discuss out approach to inference over the extracted facts.

Algorithm 1 Slot Value Extraction Pseudocode

List of entities $\mathcal{E} = \{e_0, \dots, e_{170}\}$

List of patterns $P = \{p_0, \dots, p_{|P|}\}$

List of documents containing entities $S = \{s_0, \dots, s_{|S|}\}$

```

for  $s_i \in S$  do
  for  $sentence \in s_i$  do
    for  $entity \in \mathcal{E}$  do
      if Contains( $sentence, entity$ ) then
        for  $pattern \in P$  suitable for  $entity$  do
          if Satisfies( $sentence, pattern$ ) then
            Emit( $sentence, pattern$ )

```

Rule Engine A pattern is as a record representing knowledge going to be added to a WP entity. A pattern \mathcal{P} is represented as a five-tuple $\mathcal{P} = \langle p_1, p_2, p_3, p_4, p_5 \rangle$.

The first value, p_1 represents the type of entity. These entity types are in the set $\{FAC, ORG, PER\}$ where FAC represents a type of facility, ORG represents an organization and PER represents a person. The p_2 represents a slot name. A list of slot names is present in Table 1. The third element p_3 is the pattern content — a string found

²Lingpipe (available in the dataset) provides entity tags and in-document coreference. <http://alias-i.com/lingpipe/>

Figure 2: Pattern matching for rule evaluation. The slot value is on the right side of the entity. The pattern content discovered is ‘passed away’ with a value of ‘March 2013’.

in the sentence that identifies a slot name. The extractor looks specifically for a pattern content. The pattern evaluator uses a direction (left or right) found in p_4 to explore sentence. The final element p_5 represents the slot value of a pattern. The type of slot value may be the entity type labeled by the named entity extractor, a noun phrase (NP) tagged by a part of speech tagger³ or a phrase described in the pattern list.

Figure 2 contains the example sentence from the introduction labeled by the rule engine.

There are three types of patterns distinguished by different types of slot values in the patterns. The matching methods using these three types of patterns are implemented according to the different structures of slot values.

Type I. This pattern type is driven by the entity type. For example, in pattern $\langle PER, FounderOf, founder, right, ORG \rangle$ the PER tag means the entity we are finding slot values for a PER entity; FounderOf means this is a pattern for FounderOf slot. *founder* is the anchor word we are match in a sentence; *right* means that we are going to the right part of the sentence to match the pattern and find the slot value; ORG means the slot value should be a ORG entity to the right of the entity.

Type II. This pattern type, after finding a matching pattern content, looks for a noun phrase (NP) that is representative of the slot value. For example, pattern $\langle PER, AwardsWon, awarded, right, NP \rangle$ is looking for a noun phrase after the *awarded* that may represent an award. Titles and awards are not named entity tagged hence the use of the part of speech tagger to fetch the noun phrases.

Type III. These type of facts are best discovered by hard coding the slot values. Examples of these include time phrases: $\langle PER, DateOfDeath, died, right, last\ night \rangle$. In this pattern, the phrase *last night* is exactly searched in the text last night to the right of the term *died*. This intuition behind this pattern is in news articles that report events in the past relative to the article. For example, an article will mention that a person died ‘last night’ instead of mentioning precise

³OpenNLP was used for part of speech tagging. <http://opennlp.apache.org/>

date-time information. Additionally, part of speech taggers and name entity extractors did not label these terms such as *last night* as a DATE entity.

Constraints and Inference Our data set contains some duplicate webpages, webpage texts with similar content, and some of the entity tags are incomplete. This cause some duplicates or highly similar content in the extracted list. We implement a filter to remove duplicates or the fact extractions match patterns that are general and highly susceptible to noisy. The data contains duplicates and incorrect extractions. We define rules to read ordered sets of facts to sanitize the output. The input is processed in time order, in a tuple-at-a-time fashion to allow rules to discover noisy slots that appears in close proximity. We define two classes of rules: *deduplication* and *inference* rules.

The output contains many duplicate entries. As we read the list of extracted slots we create rules to define “duplicate”. Duplicates can be present in a window of rows; we use a window size of 2 meaning we only be adjacent rows. Two rows are duplicates if they have the same exact extraction or if the rows have the same slot name and a similar slot value or if the extracted sentence for a particular slot types come from the same sentence.

New slots can be deduced from existing slots by defining inference rules. For example, two slots for the task are “FounderOf” and “FoundedBy”. A safe assumption is these slot names are biconditional logical connectives with the entities and slot values. Therefore, we can express a rule “ $X \text{ FounderOf } Y \leftrightarrow Y \text{ FoundedBy } X$ ” where X and Y are single unique entities. Additionally, we found that the slot names “Contact_Meet_PlaceTime” could be inferred as “Contact_Meet_Entity” if the Entity was a FAC and the extracted sentence contained an additional ORG/FAC tag. We also remove erroneous slots that have extractions that are thousands of characters in length or too small. Errors of extracting long sentences can typically be attributed to poor sentence parsing of web documents. We have some valid “small” extractions. For example, a comma may separate a name and a title (e.g. “John, Professor at MIT”). But such extraction rules can be particularly noisy, so we check to see if the extracted values have good entity values.

Evaluation

We evaluate the effectiveness of extracting slot values for 139 entities. We look at the baseline coverage for entities and slot names we present in a 500M page snapshot of the English web. We estimate the precision and recall of our extractions over several extracted fact.

Our system was developed on a 32-core server described in Table 2. Each document is annotated using a name entity extraction and in document coreference. A bundle of documents are serialized into chunks and encrypted. The total size of the data after compression and encryption is 4.5TB⁴. Data is ordered into 11952 date-

hour buckets ranged from 2011-10-05-00 (5th of October 2011, 12am) until 2013-02-13-23 (13th of February 2013, 11pm). The first four months of data (October 2011 - February 2012) is for training purposes, and we use this portion for rule and pattern creation and tuning. The data set contains text from several web page types as listed in Table 3.

We develop 172 extraction patterns covering each slot-name/entity-type combinations. Out of the 500 M documents and 139 entities we found 158,052 documents containing query entities, 17,885 unique extracted slot values for 8 different slots. We did not get any results from 31 entities missing and 4 slots.

In Table 4 we performed two samples of a baseline submission and estimate the correctness of the extraction. We produced accuracies in range of 54% and 55%. The errors present can be classified into two sets, incorrect entities and incorrect extractions. We found 15% and 17% incorrect entity names and we identified 27% and 30% incorrect values extracted across all entities and slot types. The majority of these errors were the result of poor extraction patterns and an incomplete alias set.

After the implementation of the baseline system, we developed an enhanced version. In this version we increased the number of extraction patterns and a generate a larger set of aliases. More detailed statistics are available in Table 5 and Table 6. Table 5 shows the recall of each slot name. Entities can have different coverages across the entire web, some are more popular such as William H. Gates or less well known such as Stevens

⁴TREC Knowledge base acceleration stream corpus

Table 4: Sampled accuracy of the results of the extracted facts.

	Correct	Incorrect Entity name	Incorrect Value
Sampling #1	55%	17%	27%
Sampling #2	54%	15%	31%

Cooperative School. Similarly slot names have various coverages — *Affiliate* is more frequent compared to *AwardsWon*. More sentences describing affiliate relationships exist across the WP entities than sentences describing awards won. The slot name *Affiliate* has been extracted the most number of times and *CauseOfDeath* was extracted the fewest with 0 instances found matching the pattern list. *AwardsWon* contained the next fewest with 38 instances found. *Affiliate* slot has a broad definition; any relation that directly connects an entity to another entity of any type can describe an *Affiliate* relationship.

To extract relationships such as *affiliate* is difficult because almost any two items can be affiliated in some way. Our patterns for this relationship led to noisy results. On the other hand for more precise slot names our accuracy increases but we have less recall. Table 6 addresses the relative accuracy measure per slot value. *AssociateOf* has the highest accuracy with 63.6% and *Affiliate*, *Contact_Meet_PlaceTime* and *EmployeeOf* have the lowest with lowest of 1%, 1% and 5% accuracy respectively. A discussion of different slots is available in literature Ellisi et al. (2012).

Discussion

Table 5 shows the distribution of extracted slot names. The number of extraction between slot names vary greatly. Some slots naturally have more results than other slots. For example *DateOfDeath* and *CauseOfDeath* have some of the fewest entities because only a few entities are deceased. Some patterns use common words as part of their patterns causing more extractions. For example, *Affiliate* looks for common words like *and* and *with* as part of the pattern content. These words are more common than *dead*, *died* or *founded* in other patterns.

Some of the entities are popular and appear at a greater frequency in the data set. For example, a ‘Corn Belt Power Cooperative’ Google search results in 86,800 documents, whereas ‘William H. Gates’ returns 3,880,000 documents. We observed that more than half of the entities appear in less than 10 documents in the data set; a large portion have appeared only once. This magnificent change in coverage supports the viability of our search and filter schemes.

Conclusions

In this paper we described an approach to perform fact extraction over one of the largest data sets to date. We generate aliases for Wikipedia entities using an API

Table 5: Recall Measure: Generic slot names like *affiliate* had the most recall, compared to less popular slot names e.g. *DateOfDeath*

Slot Name	Instances Found	Entity Coverage
<i>Affiliate</i>	108598	80
<i>AssociateOf</i>	25278	106
<i>AwardsWon</i>	38	14
<i>CauseOfDeath</i>	0	0
<i>Contact_Meet_Entity</i>	191	8
<i>Contact_Meet_PlaceTime</i>	5974	109
<i>DateOfDeath</i>	87	14
<i>EmployeeOf</i>	75	16
<i>FoundedBy</i>	326	30
<i>FounderOf</i>	302	29
<i>Titles</i>	26823	118
<i>TopMembers</i>	314	26

Table 6: Accuracy Measure: Accuracy of *AffiliateOf* was the best and *Affiliate* applied poorly due to ambiguity of being an affiliate of somebody/something

Slot Name	Correct	Wrong Entity	Incorrect Value
<i>Affiliate</i>	1%	95%	5%
<i>AssociateOf</i>	63.6%	9.1%	27.3%
<i>AwardsWon</i>	10%	10%	80%
<i>CauseOfDeath</i>	0%	0%	0%
<i>Contact_Meet_Entity</i>	21%	42%	37%
<i>Contact_Meet_PlaceTime</i>	5%	20%	85%
<i>DateOfDeath</i>	29.6%	71%	25%
<i>EmployeeOf</i>	5%	30%	65%
<i>FoundedBy</i>	62%	17%	21%
<i>FounderOf</i>	50%	0%	50%
<i>Titles</i>	55%	0%	45%
<i>TopMembers</i>	33%	17%	50%

and extract some aliases from Wikipedia pages text itself. We process documents that mention entities for slot value extraction. Slot values are determined using pattern matching over tagged entities in sentences. Finally post processing will filter, cleanup and infers some new slot values to enhance recall and accuracy.

We sampled documents from the training data period to generate an initial set of patterns and then use these patterns to generate results. After manually examining the results, we prune patterns with poor performance and add patterns that may add to extraction coverage. We use several iterations to find the best patterns.

We look to continue exploration of streaming extraction models over this large data set. Our models are simple and provide a great baseline framework to develop and compare innovative techniques.
